Number of games

In experiment 3, the 6* player games did not all have 6 players, both because games continued as participants dropped out and because if there weren't enough players after 5 minutes of waiting, the game would start with whoever was there. All analyses use "intent to treat" and call these 6 player games.

The number of games goes up in some cases because only complete blocks (where the speaker said something every trial) are analysed. If there was initial confusion and a speaker missed a trial, that block was excluded.

Table 1: The number of games in each experiment and condition. Complete games finished all 6 blocks; partial games ended early due to disconnections, but contributed at least one complete block of data. 6* indicates that some games started with fewer than 6 players or continued with fewer than 6 players after participants disconnected.

Experiment	Players	Complete	Partial	Total Participants
1: baseline	2	15	4	38
1: baseline	3	18	2	60
1: baseline	4	19	2	84
1: baseline	5	17	3	100
1: baseline	6	12	6	108
2: single speaker	6	15	3	108
2: full feedback	6	13	4	102
2: thin	6	10	6	96
3: thin	2	35	3	76
3: thin	6*	44	0	235
3: thick	2	39	3	84
3: thick	6*	38	2	222

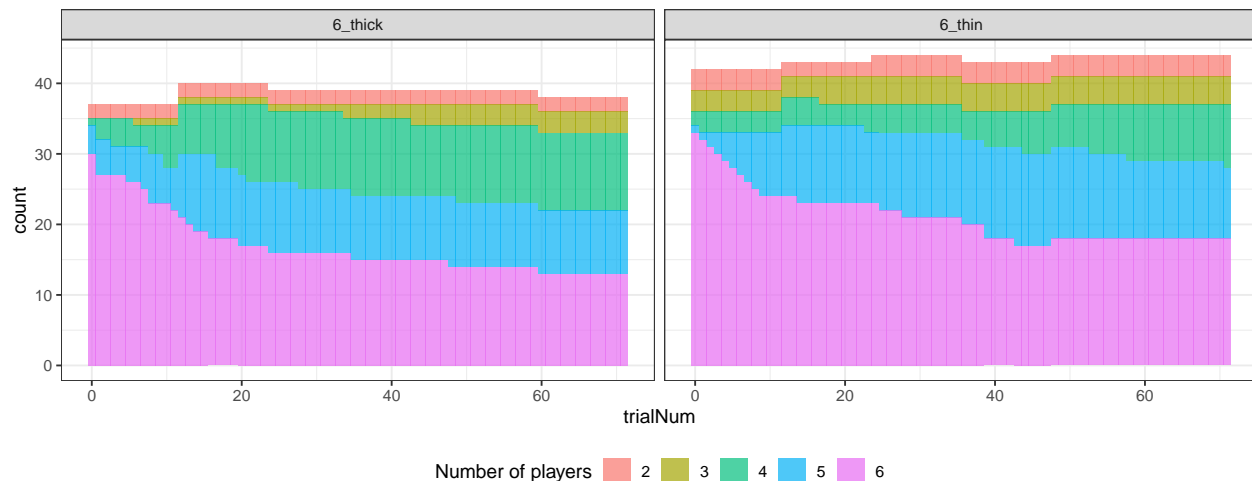

Figure 1: Number of players during 6 thin and 6 thick games in experiment 3.

More on listener utterances

Listeners in experiment 1 were. Emoji use is common in the 6 player thin games where most trials at least one listener used at least one emoji, but emoji use declines over blocks. SEE FIGURE WHATEVER IN SUPPLEMENT The use of emoji in the thin games is not directly comparable to listener contributes, since some emoji usage (such as the green checkmark) are most likely equivalent to non-referential listener language (“got it” etc.) that was excluded. The higher rate of emoji use versus referential language could be due to it’s non-equivalence, a lower level of accuracy in thin games, or emojis being a lower threshold for sending than written out questions.

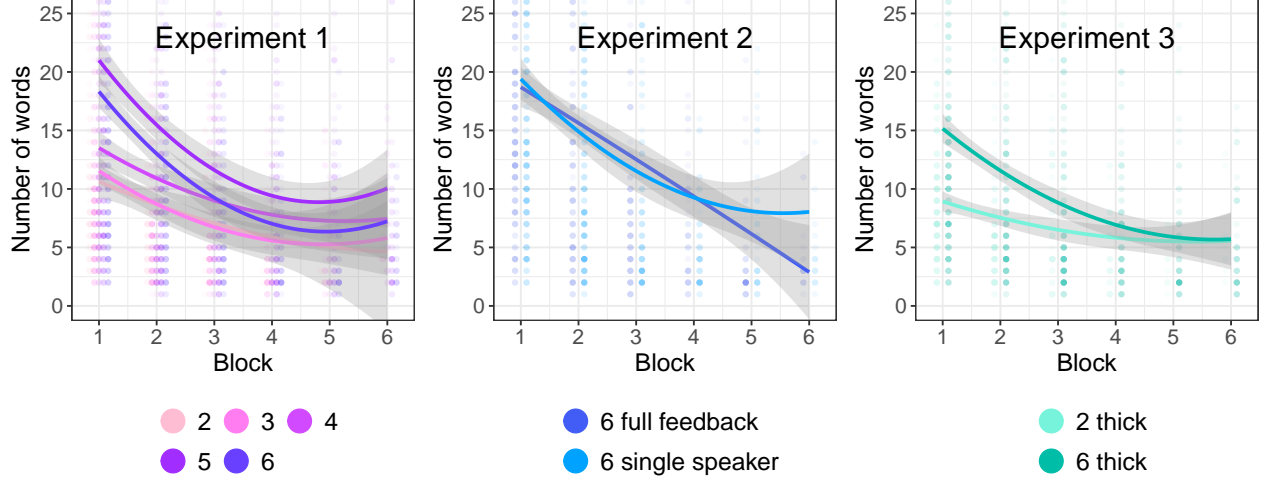

Figure 2: Number of words of referential language produced by listeners over time. Excludes trials where no listeners contributed descriptive language.

Figure 3: Fraction of trials when any reference language (or emoji) was produced by any listener.

Additional measure of convergence

Distinctiveness of tangrams

Another way of looking at how language changes over the course of the game is looking at how games start to refer to different tangrams more differently. This could reflect initial overlap in describing many figures as sitting or standing or by leg and arm and head position.

Over the course of the game, descriptions for each tangram become more distinctive (-0.043 $[-0.046, -0.039]$). In all three subexperiments, the descriptions of tangrams become more distinctive within games across time. (2a -0.046 $[-0.048, -0.044]$, 2b -0.025 $[-0.028, -0.022]$, 2c -0.025 $[-0.028, -0.022]$).

Tangram distinctiveness within games increased over time (-0.027 $[-0.029, -0.025]$). There might be more to say about other effects, but it's mostly a starting places being different in larger games and then the slopes also differ a bit?

Figure 4: Fraction of trials on which at least one listener produced the labelled emoji (or any emoji).

play with more diagrams

Comparing utterances between adjacent rounds reveals similar patterns. Thin games have lower similarity between adjacent blocks (-0.124 [-0.159, -0.088]) as do larger games (-0.034 [-0.069, 0.003]). Later in the game adjacent blocks are more similar than earlier adjacent blocks (0.046 [0.041, 0.052]), painting an overall nonlinear convergent pattern (as seen in Figure @ref(fig:other)).

Summary of model reporting

Note that for all models, block was 0 indexed, so intercepts are what happened during the first block.

Accuracy models

Accuracy models were all run as logistic models with normal(0,1) priors for both betas and sd. This model was not explicitly included in the experiment 1 and 2 pre-registrations; it was included with more ambitious mixed effects (which did not run in a timely manner) in the experiment 3 pre-reg.

Table 2: Experiment 1 logistic model of listener accuracy:
 $\text{correct.num} \sim \text{block} \times \text{numPlayers} + (1|\text{gameId})$

Term	Est.	CrI
block	0.44	[0.31, 0.58]
block:numPlayers	-0.02	[-0.05, 0.01]
Intercept	2.10	[1.57, 2.65]
numPlayers	-0.07	[-0.2, 0.05]

Figure 5: Additional measures of convergence and divergence. A is similarity to first utterance. B is similarity between utterances from adjacent blocks. C is divergence in descriptions of different tangrams within a group

Reduction models

Reduction models were run as linear models with an intercept prior of $\text{normal}(12,20)$, a beta prior of $\text{normal}(0,10)$, an sd prior of $\text{normal}(0,5)$ and a correlation prior of $\text{lkj}(1)$. This model was pre-registered for each experiment and run with the mixed effects structure as prespecified.

Table 3: Experiment 2: 6 single speaker logistic model of listener accuracy:
 $\text{correct.num} \sim \text{block} + (1|\text{gameId})$

Term	Est.	CrI
block	0.45	[0.39, 0.52]
Intercept	1.78	[1.4, 2.19]

Table 4: Experiment 2: 6 full feedback logistic model of listener accuracy:
 $\text{correct.num} \sim \text{block} + (1|\text{gameId})$

Term	Est.	CrI
block	0.47	[0.39, 0.54]
Intercept	1.35	[0.59, 2.06]

Table 5: Experiment 2: 6 thin logistic model of listener accuracy:
 $\text{correct.num} \sim \text{block} + (1|\text{gameId})$

Term	Est.	CrI
block	0.23	[0.19, 0.28]
Intercept	0.88	[0.64, 1.12]

Table 6: Experiment 3 logistic model of listener accuracy:
 $\text{correct.num} \sim \text{block} \times \text{gameSize} \times \text{channel} + (1|\text{gameId})$

Term	Est.	CrI
block	0.41	[0.32, 0.5]
block:channelthin	-0.07	[-0.18, 0.04]
block:gameSize6	-0.34	[-0.43, -0.25]

numPlayers	2.12	[1.03, 3.12]

Table 14: Experiment 1: is.words \sim block \times numPlayers + (1|gameId)

Term	Est.	CrI
block	-0.80	[-0.97, -0.63]
block:numPlayers	0.03	[0, 0.07]
Intercept	-2.65	[-3.5, -1.83]
numPlayers	0.78	[0.58, 0.98]

SBERT models

For all of the models of sbert similarity, we used linear models with the priors $\text{normal}(.5, .2)$ for intercept, $\text{normal}(0, .1)$ for beta, and $\text{normal}(0, .05)$ for sd.

These models were verbally described (but not formally specified) in the pre-registrations for experiment 2 in the full feedback and thin conditions and for experiment 3, for looking at divergence between games, convergence within games (compare to first, next, and last), and divergence between tangrams within games.

Convergence within games: comparison to last round

This is the convergence metric presented in the paper.

Table 15: Experiment 1:sim \sim earlier \times condition + (1|tangram) + (1|gameId)

Term	Est.	CrI
condition	-0.008	[-0.021, 0.005]
earlier	0.089	[0.076, 0.102]
earlier:condition	-0.008	[-0.011, -0.005]
Intercept	0.517	[0.458, 0.573]

Table 16: Experiment 2: 6 single speaker:sim \sim earlier + (1|tangram) + (1|gameId)

Extra emoji analysis

Written about 6thin in experiment 2 and for 2 and 6 thin in 3. Additionally, exclusive to this condition, we will analyse the distribution of emoji's produced as a function of block and its relation to accuracy and speaker utterance length.
